Creep: Slime Mold Network Builder

A slime mold growth simulator of sorts with a large-scale twist

The project will be a game/simulator of slime mold growth where the goal is to get the slime mold to build a network and creep from city to city by spending a limited budget to either put food and entice the slime mold or putting toxins to guide it into a path you want. The plan is to have blind agents spreading independently similar to how a slime mold does. The agents will smell in front of them at the front-right, front-left and center directions and will go in the direction of the strongest smell and leave their own smell behind with them. I'd expect to see there be initial wide spread growth then as the time goes on the paths become optimized and the straight paths grow stronger similar to in this slime mold timelapse video https://www.tiktok.com/@karl.barx/video/7579917441082428702?is_from_webapp=1&sender_device=pc the paths between food grow stronger as the time goes on and the other paths are not as visible. It will be displayed in the terminal with a grid output.

To show the level of detail I would like the grid will have to be a decent size which could lead to computing issues which would require me to scale down the grid and lower the detail.
